

THE 5 RIGHTS OF CARE EXECUTION™

What could earlier, targeted action be worth?

Your population. Your care pathway. Your operating assumptions.

\$674,125

Modeled net annual savings | 100,000 lives | illustrative base case

Pathway volume	$100,000 \text{ lives} \times 0.75 \text{ episodes/year} = 75,000 \text{ episodes}$
Execution delay	$15\% \text{ delayed} = 11,250 \text{ episodes}$
Early visibility	$60\% \text{ detectable early} = 6,750 \text{ signals}$
Reach + resolution	$70\% \text{ reached; } 20\% \text{ resolved} = 945 \text{ resolutions}$
Modeled value	$945 \times \$1,000 \text{ avoided cost} = \$945,000 \text{ gross value}$
Program cost	$4,725 \text{ reaches} \times \$15 + \$200,000 \text{ fixed} = \$270,875$
Net annual value	$\$945,000 - \$270,875 = \$674,125$

All inputs are assumptions pending partner validation. The conservative scenario yields a \$175,000 loss; economic value depends on reach, effective intervention, avoided cost, and program cost. The model does not demonstrate real-world ROI or establish savings versus your current model.

Which of these assumptions holds in your population?

Let's compare the scenario with your baseline and identify what a focused pilot should measure.
